

# **Gunshot Detection in Video Games**

# Amit Ben Aroush and Asaf Arad, Supervised by Hadas Ofir

In collaboration with WAVES

#### Introduction

Gunshot detection is a Feature that upgrades the gaming experience.

#### **The Database**

- Extract features:
  - Correlation with sample

#### **Transfer Learning**

Common way to use pre-trained CNNs as an initialization for the task of interest.

- Helps dealing with unseen/hidden enemies.
- Gunshots detection systems already exist in real world for security.

#### Goals

- Automatic system for real-time acoustic detection of gunshots in video games.
- Generic gunshot in generic video game.
- We wish to prove the feasibility of using deep-learning methods for detection of generic gunshot in video games.

### Challenges

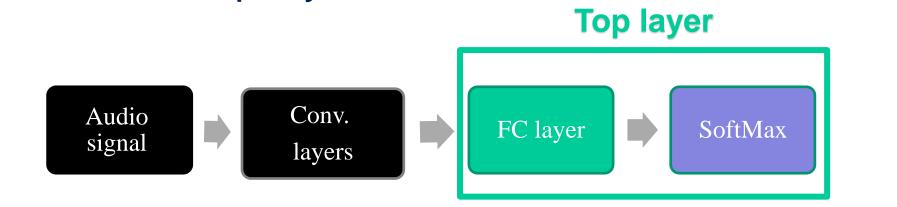

- Lack of labeled datasets.
- Restricted sounds in video games.
  - Variety of sound.
- Fixed synthesized sound patterns.
- Multiple gunshots in a frame-bursts.

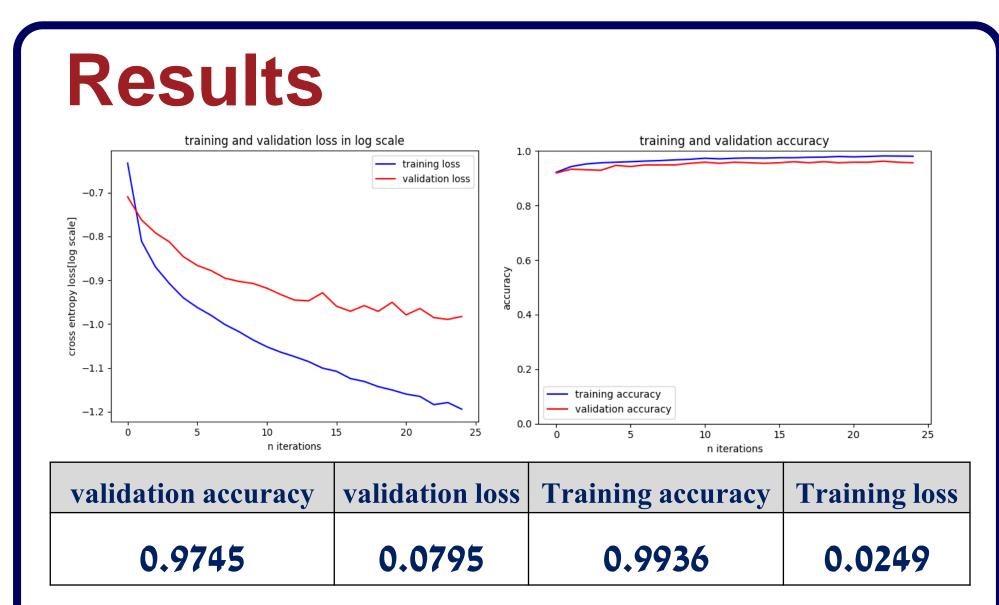

# **Chosen Solution**

- Energy
- Spectrogram features
- MFCC
- Intersection between the classifier labeling and the manual labeling we performed.
- The database was adapted in its characteristics to the database on which the network was trained:
  - Raw data.
  - Resample to 16KHz.
- Data augmentation:
  - Reverberation.
  - White Noise.
- The dataset for training and testing the network: 2843 frames, contains 1100 gunshot frames and 1743 non-gunshot frames.

# **YAMnet Model**

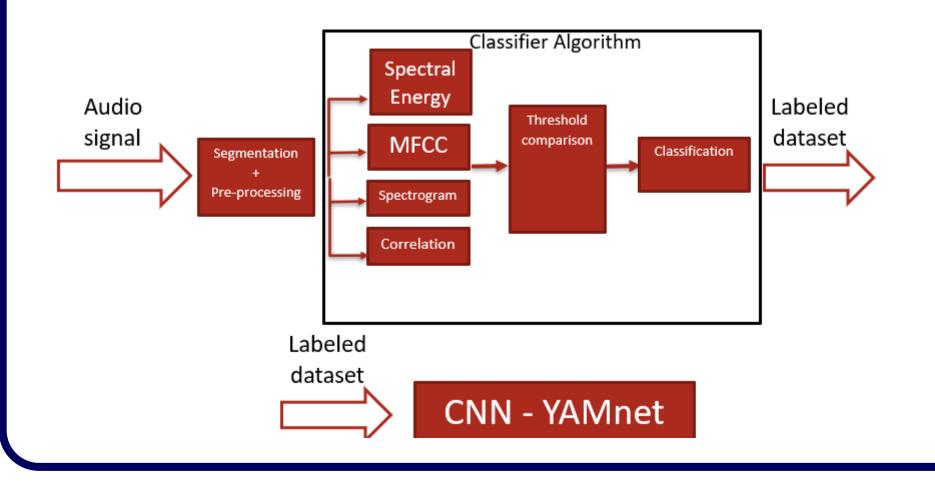

- Fine-tuning:
- CNN layers are fixed.
- Replace the classifier on top of the CNN
  - top layers contain high level features.
- Train top layer.

In order to test the quality of the chosen solution, we compared it with different solutions:

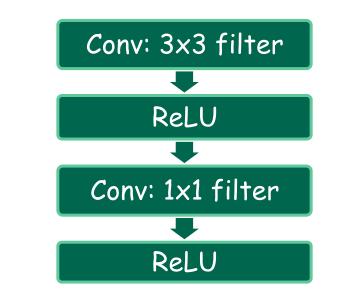

- Manual analysis of basic examples.
- Build a classifier algorithm that pre-processes the data and selects optimal classification features.
- Building the Dataset.
- Use a pre-trained network and alter it to classify gunshots using transfer learning.
  - Convolution network called YAMnet.

# **Network I/O**

- System's input: audio waveform signal.
- Waveform is converted to Mel-spectrogram, which is the input to the network layers.

- CNN for acoustic classification:
  - Separable convolutional inner layer

- Fully connected output layer
- SoftMax activation
- 521 event classes

#### **Fine tuning** in this project:

- SVM with linear kernel
  - Features from our dataset.
- YAMnet without fine tuning
  - 9 classes for gunshot.
  - 512 classes for non-gunshot.

Num	Solution	Accuracy	Precision	Recall
1	YAMnet with fine tuning	0.9708	0.9576	0.9576
2	SVM with linear kernel	0.99	0.99	0.99
3	YAMnet without fine tuning	0.8333	0.9296	0.5593

## Conclusions

- Our goal was to build a real time system for acoustic detection of gunshots in video games.
- We built a labeled Dataset.

After the SoftMax layer, the classification output of the class with the maximum probability is chosen.

- Extract the top FC layer.
- Define the top layer- FC layer for binary classification.
  - -- Input 1024 patches of 96X64.
- SoftMax activation.
- **Training** the fully connected layer:
- SGD optimizer.
- Cross-entropy loss.
- 1E-4 learning rate.
- 1 batch size.
- 64% training, 16% validation, 20% test.
- 25 epochs.

- most significant characteristics are correlation and spectrogram.
- Least significant characteristic is energy.
- We succeeded in building a deeplearning based system that qualifies the project's requirements.

### **Future Work**

- Expand the project's goal to localize gunshots.
- Expand the variety of gunshot types in video games.
